

What it does `summarizeChanges` builds a human-readable summary of file changes from a `ChangeAnalysis` object. It reports how many files were added, removed, or structurally modified, returning a comma-separated string such as `"3 new,1 deleted,2 modified"`.

How it works1. Initialize an empty array `parts` .2. **Check each change category*

- in order: - If `analysis.newFiles.length > 0` , push a string like `"N new"` into `parts` . - If `analysis.deletedFiles.length > 0` , push `"N deleted"` . - If `analysis.structurallyChangedFiles.length > 0` , push `"N modified"` .3. **Return*
- the joined string `parts.join(", ")` .The function relies solely on the lengths of the three arrays in `analysis` ; no other side effects occur.

Notes for reviewers- The function assumes `analysis` always contains the three arrays; missing properties would cause a runtime error.- It does not handle pluralization beyond the fixed suffixes (`new` , `deleted` , `modified`).- The order of categories is fixed; if a new category is added later, the order may need updating.- No external dependencies or state changes are involved, making the function pure and easy to test.
