Overview

A new hook `useLiquidGlassHost` is added to `packages/graph-view/src/hooks/useLiquidGlassHost.ts` (lines 1-16). It tracks whether the document is in macOS liquid-glass mode and triggers a re-render when the mode toggles.

Key changes

- **Imports** ```ts import { useEffect, useState } from "react"; import { isLiquidGlassHost } from "../themes/theme-engine.ts";

```
- **Hook export** ts export function useLiquidGlassHost(): boolean - **State initialization**  
- the initial value reflects the current mode: ts const [active, setActive] =  
  useState(isLiquidGlassHost); - **Effect** - a MutationObserver watches  
  document.documentElement for changes to the class attribute and updates active: ts  
  useEffect(() => { const root = document.documentElement; const sync = () =>  
    setActive(isLiquidGlassHost()); sync(); const observer = new MutationObserver(sync);  
    observer.observe(root, { attributes: true, attributeFilter: ["class"] }); return () =>  
      observer.disconnect(); }, []); ``` - **Return value** - the hook returns the current active boolean.
```

Impact

- **Re-rendering** – components using the hook re-render only when liquid-glass mode changes.
- **Centralization** – mode detection logic is encapsulated in one place; changes to `isLiquidGlassHost` automatically propagate.
- **Efficiency** – the observer monitors only the `class` attribute, limiting DOM traversal.

Risks & follow-ups

- **Dependency array** – the `useEffect` has an empty array; if `isLiquidGlassHost` changes implementation, the hook may not react.
- **Observer overhead** – observing `document.documentElement` could be costly on very large DOM trees; benchmark on target devices.
- **Cleanup** – ensure `observer.disconnect()` runs on component unmount; test unmount scenarios.
- **Cross-browser support** – verify `MutationObserver` behaves consistently in all target browsers, especially Safari on macOS.
