What it does `PrefetchSummaryQueueOut` aggregates the results of a pre-fetch operation that prepares jobs for a diff comparison.- `queue` holds the prioritized jobs that will actually be processed, truncated to a configurable `limit` to keep IPC payloads small.- The remaining fields (`input_changes` , `skipped_gitignore` , `skipped_novadiff_docs` , `skipped_non_text` , `eligible_changes` , `returned`) are integer counters that record how many rows were received, filtered, or ultimately returned.

How it worksDuring pre-fetch, each row from the compare engine is examined.1. `input_changes` is incremented for every row received.2. Rows that match a `.gitignore` or `.git/info/exclude` rule are counted in `** skipped_gitignore *`

- and omitted from further processing.3. Rows whose path falls under the `novadiff-docs/` bundle are counted in `skipped_novadiff_docs` .4. Rows that are binary or not valid UTF-8 are counted in `skipped_non_text` .5. After these filters, the remaining rows are considered **eligible**; their count is stored in `eligible_changes` .6. Jobs are then created for each eligible row, prioritized, and pushed into `** queue *`
- until the `limit` is reached.7. `** returned *`
- mirrors `queue.len()` to confirm how many jobs were actually handed off.

Notes for reviewers- The struct itself contains no logic; it is purely a data container.- The snippet does not show how `limit` is defined or how the prioritization algorithm works—those details are elsewhere.- It is unclear whether `eligible_changes` includes rows that were later dropped due to the `limit` ; the comment suggests it counts rows *after*

- gitignore and docs filtering but *before*
- truncation.- No visibility modifiers are shown; assume the struct is public to the IPC boundary.
