What it does `clearSummaryPrefetchCache` is a small utility that empties the pre-fetch cache for summary data. When invoked, it removes every entry stored in the `summaryByPath` collection, effectively resetting the cache so that subsequent summary requests will be fetched anew.

How it works The function body consists of a single statement:

`summaryByPath` is an object that supports a `clear()` method—most likely a `Map` or a custom cache implementation. Calling `clear()` deletes all key/value pairs from that collection. Because the function takes no parameters and returns nothing, its sole side effect is the mutation of `summaryByPath`. No error handling is present, so if `summaryByPath` is undefined or does not implement `clear()`, a runtime exception would be thrown.

Notes for reviewers

- The snippet does not show where `summaryByPath` is defined; it is assumed to be in scope (e.g., a module-level variable).
- No export statement is visible, so it may be an internal helper or exported elsewhere.
- The function has no dependencies other than `summaryByPath`; it is pure in the sense that it only mutates that object.
- Consider adding a return value (e.g., the number of entries cleared) or error handling if the cache may be in an unexpected state.
- If this function is part of a public API, documenting its effect on the cache would aid callers.
