Overview

This is a **selected region of a file diff** for the `src/components/CodeCityView.tsx` file in the NovaDiff repository. The selected region includes changes to the `CodeCityView` component, specifically the addition of a new `onPointerDown` event listener to the `renderer.domElement`. This event listener is used to detect mouse clicks on the rendered scene and trigger the `onSelect` callback with the building that was clicked.

Selected change

The selected change is the addition of a new `onPointerDown` event listener to the `renderer.domElement`. This event listener is triggered when the user clicks on the rendered scene and is used to detect which building was clicked. The `onSelect` callback is then called with the building that was clicked.

Semantic context

The `CodeCityView` component is responsible for rendering the 3D visualization of the code city layout. The `onPointerDown` event listener is added to the `renderer.domElement` to detect mouse clicks on the rendered scene and trigger the `onSelect` callback with the building that was clicked.

Risks & follow-ups

The addition of this event listener introduces a potential risk in terms of performance, as it may result in increased CPU usage if the `onSelect` callback is computationally expensive. Additionally, the `onPointerDown` event listener may not be triggered correctly if the user interacts with the rendered scene in a way that does not correspond to a building.

To mitigate these risks, it would be beneficial to perform some performance testing to ensure that the `onPointerDown` event listener does not significantly impact performance. Additionally, it would be helpful to ensure that the `onPointerDown` event listener is triggered correctly for all types of interactions with the rendered scene, including those that do not correspond to buildings.
