Overview

The `ElectronAPI` interface in `src/vite-env.d.ts` has been extended with five new methods that expose additional Git and snapshot functionality to the renderer process. The changes are located in the file's latter section (lines 293-301 and 347-354).

Key changes

- `gitStagePaths` (lines 293-294) – stages a list of file paths in a repository and returns the number of files staged.
- `gitStageDistrict` (lines 295-297) – stages all files under a specified directory subtree and reports the staged count.
- `exportProjectSnapshot` (lines 298-301) – creates a ZIP archive of a project snapshot, returning the ZIP path and byte size.
- `gitCommitDetail` (lines 347-350) – retrieves detailed commit information for a given hash.
- `githubCommitContext` (lines 351-354) – fetches GitHub commit context data for a repository and SHA.

Impact

These additions give the renderer process direct access to:

- Programmatic staging of files or directories, enabling UI-driven Git workflows.
 - Exporting a project snapshot for backup or sharing.
 - Inspecting commit metadata and GitHub context without additional API calls.
- The interface changes are purely type declarations; actual implementation must exist in the main process to make the calls functional.

Risks & follow-ups

- **Implementation gap** – the new methods are only declared; if the main process lacks corresponding handlers, calls will fail.
- **Security** – exposing Git staging and snapshot export may require permission checks; review access controls.
- **Testing** – add unit and integration tests to verify that the renderer can invoke these methods and that the returned data matches expectations.
- **Documentation** – update API docs and example usage to reflect the new capabilities.

Unknown from the available diff/scan evidence: whether the main process has been updated to support these calls.
