Overview

A new file `packages/graph-view/src/themes/theme-engine.ts` introduces a lightweight theme system.

It defines a `hexToRgb` helper (R4-R7), a `deriveFromAccent` routine that builds RGBA values from an accent hex and dark-mode flag (R10-R30), and two public functions: `applyTheme` (R34-R69) and `clearTheme` (R72-R90). The file imports the `ThemeConfig` type from `./types.ts` and the `getAccent` / `getPreset` helpers from `./presets.ts` (R1-R2).

Key changes

- **Imports** – `ThemeConfig` and preset helpers added (R1-R2).
- **Utility** – `hexToRgb` converts a hex string to an RGB string (R4-R7).
- **Derived values** – `deriveFromAccent` returns a record of RGBA strings based on an accent hex and a dark-mode flag (R10-R30).
- **Theme application** – `applyTheme` writes preset colors, accent colors, derived values, a `data-theme` attribute, and a heading-font CSS variable to the target element's style (R34-R69).
- **Teardown** – `clearTheme` removes all CSS variables written by `applyTheme` and the `data-theme` attribute (R72-R90).

Impact

- **Centralization** – Theme logic is now in a single module, reducing duplication across components.
- **Simplicity** – Operations are straightforward DOM style updates; the code uses only standard CSS custom properties and attributes.
- **Extensibility** – Future presets or accent logic can be updated in one place.

Risks & follow-ups

- `hexToRgb` may misbehave with malformed hex strings (e.g., missing `#` or wrong length).
- `clearTheme` must remove every property set by `applyTheme` ; missing keys could leave stale styles.
- Verify that `applyTheme` respects the default `target` (`document.documentElement`) when invoked from a standalone graph view.
- Run linting and unit tests to catch any type mismatches introduced by the new imports.
