Overview

A new file `src/components/AutoCommitWorkspace.tsx` (lines 1-387) introduces a React component that combines Git status, LLM-generated commit messages, optional documentation bundles, and GitHub PR creation into a single UI.

Key changes

- **Imports** (lines 1-9): React hooks, Lucide icons, and app modules (`commitMessage` , `docWorkspaceMetrics` , `llmStorage` , `types` , `gitTypes`).
- **Props interface** `AutoCommitWorkspaceProps` (lines 12-21) declares `suggestedRepoPath` , `compared` , `compareRows` , `leftRoot` , `rightRoot` , `leftTitle` , `rightTitle` , and `llmSettings` .
- **Component** `AutoCommitWorkspace` (lines 25-381) manages state for repo root, Git status, preview, draft generation, publishing, and UI step (`draft` , `review` , `done`). It uses `window.electronAPI` methods:
 - `refreshRepo` calls `api.gitRepoStatus` (line 67) and `api.gitPublishPreview` (line 70).
 - `generateDraft` calls `api.llmSummarize` (line 112) and optionally `api.writeNovadiffDocs` (line 129).
 - `executePublish` calls `api.gitPublishExecute` (line 168).
- **Helper** `pathBasename` (lines 383-387) extracts the last segment of a path for labeling.

Impact

- Adds runtime dependencies on `window.electronAPI` ; missing any of the referenced APIs will surface as runtime errors.
- Heavy work (LLM summarization, metric calculation) runs inside callbacks; if these operations block the event loop, the UI may freeze until completion.

Risks & follow-ups

1. **API availability** – Verify that `gitRepoStatus` , `gitPublishPreview` , `llmSummarize` , `writeNovadiffDocs` , and `gitPublishExecute` exist on `window.electronAPI` .
2. **Type mismatches** – Ensure `GitRepoStatus` , `PublishPreview` , and `FileChange` types match the actual API responses.
3. **LLM failure** – `parseCommitMessageOutput` (imported from `commitMessage`) may throw; confirm graceful error handling.
4. **UI blocking** – Monitor for freezes during draft generation; consider adding a spinner or off-loading heavy work.
